GT 4.2.0 Java WS A&A Admin Guide

Introduction

This guide contains advanced configuration information for system administrators working with Java WS A&A. It provides references to information on procedures typically performed by system administrators, including installing, configuring, deploying, and testing the installation.

⚠️ Important

This information is in addition to the basic Globus Toolkit prerequisite, overview, installation, security configuration instructions in the Installing GT 4.2.0. Read through this guide before continuing!

Authentication/message protection issues. The main administration issues for authentication/message-protection deal with configuring credential-related settings. There are multiple mechanisms for doing this:

• Security Descriptors (This is the preferred mechanism)
  • Container Security Descriptor
  • Service Security Descriptor
• CoG properties
• Environment variables
• Relying on default behavior. The only default behaviors available concern the proxy file and trusted certificates locations.

Authorization issues. Authorization in Java WS A&A is enforced on the server and the client side. Admin configuration could include determining the container/service level authorization mechanism and setting up and managing authorization policy, e.g. entries in grid map file and so on. The Chapter 2, Configuring chapter describes how to configure Java WS A&A descriptors.

Chapter 1. Building and Installing

This component is built and installed as a part of Java WS Core. See "Building and Installing" in the Java WS Core Admin Guide for more information.
Chapter 2. Configuring

Java WS A&A is configured using security descriptors. The following describes configuration settings specific for authorization and authentication. You can read the entire Java WS A&A Security Descriptor documentation here.

- Configuring authorization
- Configuring authentication/message protection

1. Configuring authorization

1.1. Configuration overview

Security descriptors are mechanisms used to configure authorization mechanism and policy. The authorization on the server side can be configured at the container, service or resource level.

On the client side, authorization can be configured using security descriptors or as a property on the stub. This configuration can be done on a per invocation granularity

1.2. Server side authorization

The server side authorization can be configured at the container, service or resource level using

- Security descriptors using files. Refer to Section 1, “Configuring Using Files”
- Security descriptors programmatically. Refer to Section 2, “Configuring Programmatically.”

To write and configure a server-side custom authorization mechanism refer to Section 2.3, “Writing a custom server-side authorization mechanism”.

1.3. Client side authorization

The client side authorization can be configured for each invocation.

- Security descriptors using files. Refer to Section 1, “Configuring Using Files”, specifically Section 1.2.2, “Configuring authorization mechanism”.
- Security descriptors programmatically. Refer to Section 2, “Configuring Programmatically.”
- Properties on the Stub. Refer to Section 2.1, “Configuring client-side authorization on the stub”

To write and configure custom authorization mechanism refer to Section 2.2, “Writing custom client-side authorization scheme”.

If no authorization mechanism has been specified, HostOrSelf authorization is used. In this scheme host authorization is tried first, if it fails, self authorization is attempted.
2. Configuring authentication/message protection

2.1. Configuration overview

Configuration of service-side security settings can be achieved by using container or service security descriptor. Some of the security configuration, like the credential to use and trusted certificates location, can also be configured using CoG properties or rely on default location. **The preferred way is to provide these settings in a security descriptor.**

The next section provides details on the relevant properties. An overview of the syntax of security descriptors can be found in Java WS A&A Security Descriptor Framework. Available CoG security properties can be found in Chapter 2, Configuring.

2.2. Syntax of the interface

The following properties are relevant to authentication and message/transport security:

<table>
<thead>
<tr>
<th>Table 2.1. Configuring server side authentication and message/transport security</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Number</strong></td>
</tr>
</tbody>
</table>
| 1 | Credentials | Container or service descriptor configuration | • X509_USER_CERT or CoG Configuration: User certificate configuration
• X509_USER_KEY or CoG Configuration: User key configuration
• X509_USER_PROXY or CoG Configuration: User proxy configuration  
If no explicit configuration is found, the default proxy is read from /tmp/x509_up_<uid>. |
| 2 | Trusted Certificates | Container security descriptor configuration | CoG Configuration |
| 3 | Limited proxy policy configuration | Container or service descriptor configuration | None. |
| 4 | Replay Attack Window | Container or service descriptor configuration | None. |
| 5 | Replay Attack Filter | Container or service descriptor configuration | None. |
| 6 | Replay timer interval | Container descriptor configuration | None. |
| 7 | Context timer interval | Container descriptor configuration | None. |
Chapter 3. Deploying

This component is deployed as a part of Java WS Core.
Chapter 4. Testing

To execute security tests ensure that Ant with JUnit is configured.

All the security tests require a valid credential. Refer to Security section of GT Administrator guide for details on acquiring credentials.

The security tests are included in $GLOBUS_LOCATION/lib/wsrfs_test_unit.jar. This jar contains tests for both the Java WS Core component and the WS Authentication and Authorization components contained in the Java WS Core package.

To execute the tests, pass the above jar file to the test script as described in Section 12.3, “How do I run my JUnit tests for Java WS Core and/or my services?”. To ensure that only security tests are run, set -DsecurityTestsOnly=true.

By default the tests require that the container and the tests use the same credentials, i.e self authorization is done on secure calls.

The tests allow for another configuration in which the container can be configured with host credentials and the tests can be run with any credentials.

- Configure the container to use host credentials using the security descriptor as described in the container descriptor section.
- Edit $GLOBUS_LOCATION/etc/globus_wsrfs_test_unit/server-config.wsdd.
  - Comment out the configured descriptor in SecurityTestService, RParamTestService and AuthzCalloutTestService that specifies self authorization.
    <!-- Does self authz by default -->
    <!-- parameter name="securityDescriptor" value="@config.dir@/security-config.xml"/ -->
  - Uncomment the configuration for identity authorization.
    <!-- For use only when identity authz is used-->
    <parameter name="securityDescriptor"
    value="@config.dir@/identity-security-config.xml"/>

  - In $GLOBUS_LOCATION/etc/globus_wsrfs_test_unit/identity-security-config.xml, set the value of the property identity to the subject DN of the credentials used to run the tests.
    <!-- set to expected identity -->
    <param:parameter name="identity"
    value="Identity used by client"/>
  - Edit $GLOBUS_LOCATION/etc/globus_wsrfs_test_unit/test-container-security-config.xml to add the following element, before <reject-limited-proxy value="true"/>
• Start a secure and insecure standalone container.

```bash
$ cd $GLOBUS_LOCATION
$ bin/globus-start-container -nosec
```

On another window,

```bash
$ cd $GLOBUS_LOCATION
$ bin/globus-start-container
```

• To run tests against external containers, secure and insecure, on localhost ports 8180 and 8181 respectively, the command would be:

```bash
ant -f share/globus_wsrf_test/runtests.xml runServer
-Dtests.jar=$GLOBUS_LOCATION/lib/wsrf_test_unit.jar
-DsecurityTestsOnly=true
-Djunit.jvmarg=-Dsecurity.test.client.authz=host
-Dsecurity.test.authz.identity="container/subject/DN"
-Dsecurity.test.cert="/server/public/certificate"
-Dsecurity.test.key="/server/key/file"
-Dtest.server.url=http://127.0.0.1:8181/wsrf/services/
-Dsecure.test.server.url=https://127.0.0.1:8180/wsrf/services/
```

• For example, if the container security descriptor has credentials configured as `/etc/grid-security/containercert.pem` and `/etc/grid-security/containerkey.pem` and the DN of the credential is `/DC=org/OU=Services/CN=-testDN/CN=some.host.edu`, the command to run would be:

```bash
ant -f share/globus_wsrf_test/runtests.xml runServer
-Dtests.jar=$GLOBUS_LOCATION/lib/wsrf_test_unit.jar
-DsecurityTestsOnly=true
-Djunit.jvmarg=-Dsecurity.test.client.authz=host
-Dtest.server.url=http://127.0.0.1:8181/wsrf/services/
-Dsecure.test.server.url=https://127.0.0.1:8180/wsrf/services/
-Dsecurity.test.authz.identity="/DC=org/OU=Services/CN=-testDN/CN=some.host.edu"
-Dsecurity.test.server.cert="/etc/grid-security/containercert.pem"
```

```xml
<credential>
  <cert-key-files>
    <key-file value="path to container key"/>
    <cert-file value="path to container cert"/>
  </cert-key-files>
</credential>
```
-Dsecurity.test.server.key="/etc/grid-security/containerkey.pem"
-Dsecurity.test.enc.cred="/etc/grid-security/containercert.pem"
Chapter 5. Security Considerations

1. Security considerations for Java WS A&A

1.1. Security considerations for authorization

1.1.1. Client side authorization

Client authorization of the server is done after the completion of the operation when GSI Secure Message authentication
is used. If you require client authorization to be done prior, use GSI Secure Conversation or GSI \textit{Transport security}.

1.1.2. Host authorization

During host authorization, the toolkit treats DNs "hostname-*.edu" as equivalent to "hostname.edu". This means that
if a service was setup to do host authorization and hence accept the certificate "hostname.edu", it would also accept
certificates with DNs "hostname-*.edu".

The feature is in place to allow a multi-homed host following a "hostname-interface" naming convention, to have a
single host certificate. For example, host "grid.test.edu" would also accept likes of "grid-1.test.edu" or "grid-foo.test.edu".

\begin{itemize}
\item \textbf{Note}
\begin{itemize}
\item The wildcard character "*" matches only name of the host and not domain components. This means that
"hostname.edu" will not match "hostname-foo.sub.edu", but will match "host-foo.edu".
\end{itemize}
\end{itemize}

\begin{itemize}
\item \textbf{Note}
\begin{itemize}
\item If a host was set up to accept "hostname-1.edu", it will not accept any of "hostname-*.edu".
\end{itemize}
\end{itemize}

A bug\footnote{\url{http://bugzilla.globus.org/bugzilla/show_bug.cgi?id=2969}} has been opened to see if this feature needs to be modified.

1.2. Security considerations for Message/Transport-level Security

1.2.1. File permissions

The Java security code currently does not enforce secure permissions and, implicitly, file ownership requirements on
any of the security related files, e.g. configuration and credential files. It is thus important that administrators ensure
that the relevant files have correct permissions and ownership. Permissions should generally be as restrictive as possible,
i.e. \textit{private keys} should be readable only by the file owner and other files should be writable by owner only, and the
files should generally be owned by the globus user (the requirements that the C code enforces are documented in
\textit{Configuring GSI}).

Also refer to \textbf{Section 5. “Known Problems”} for details on any other open issues.
Chapter 6. Debugging

Because Java WS A&A is built on Java WS Core, it uses the same sys admin logging, described below:

1. Logging in Java WS Core

The following information applies to Java WS Core and all services built on Java WS Core.

Java WS Core server side has two types of loggers. One logger is used for development logging and by default writes to standard out. The other logger includes system administration information and is CEDPs best practices compliant. On client side, only developer logging is available and is configured using log4j.properties.

1.1. Development Logging in Java WS Core

The following information applies to Java WS Core and those services built on it.

Logging in the Java WS Core is based on the Jakarta Commons Logging API. Commons Logging provides a consistent interface for instrumenting source code while at the same time allowing the user to plug-in a different logging implementation. Currently we use Log4j as a logging implementation. Log4j uses a separate configuration file to configure itself. Please see Log4j documentation for details on the configuration file format.

1.1.1. Configuring server side developer logs

Server side logging can be configured in $GLOBUS_LOCATION/container-log4j.properties, when the container is stand alone container. For tomcat level logging, refer to Logging for Tomcat. The logger log4j.appender.A1 is used for developer logging and by default writes output to the system output. By default it is set for all warnings in the Globus Toolkit package to be displayed.

Additional logging can be enabled for a package by adding a new line to the configuration file. Example:

```
# for debug level logging from org.globus.package.FooClass
log4j.category.org.globus.package.name.FooClass=DEBUG

# for warnings from org.some.warn.package
log4j.category.org.some.warn.package=WARN
```

1.1.2. Configuring client side developer logs

Client side logging can be configured in $GLOBUS_LOCATION/log4j.properties. The logger log4j.appender.A1 is used for developer logging and by default writes output to the system output. By default it is set for all warnings in the Globus Toolkit package to be displayed.

---

1 http://cedps.net/index.php/LoggingBestPractices
2 http://jakarta.apache.org/commons/logging/
3 http://logging.apache.org/log4j/
5 http://tomcat.apache.org/tomcat-5.5-doc/logging.html
1.2. Configuring system administration logs

The specific logger to edit will be log4j.logger.sysadmin in $GLOBUS_LOCATION/container-log4j.properties. There you can configure the following properties:

```java
log4j.appender.infoCategory=org.apache.log4j.RollingFileAppender
  log4j.appender.infoCategory.Threshold=INFO
  log4j.appender.infoCategory.File=var/containerLog
  log4j.appender.infoCategory.MaxFileSize=10MB
  log4j.appender.infoCategory.MaxBackupIndex=2
```

Above implies the logging file is rolling with each file size limited to 10MB and the logging information is stored in $GLOBUS_LOCATION/var/containerLog.

1.3. Sample log file

The sample log file\(^6\) contains many log entries for various scenarios in the Java WS container.

\(^6\) [http://www.globus.org/toolkit/docs/4.2/2.0/common/javawscore/sample-container-log.txt](http://www.globus.org/toolkit/docs/4.2/2.0/common/javawscore/sample-container-log.txt)
Chapter 7. Troubleshooting

For a list of common errors in GT, see Error Codes.

1. Credential Troubleshooting

1.1. Credential Errors

The following are some common problems that may cause clients or servers to report that credentials are invalid:

For a list of common errors in GT, see Error Codes.
### Table 7.1. Credential Errors

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Definition</th>
<th>Possible Solutions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Your proxy credential may have expired</td>
<td>Your proxy credential may have expired.</td>
<td>Use grid-proxy-info to check whether the proxy credential has actually expired. If it has, generate a new proxy with grid-proxy-init.</td>
</tr>
<tr>
<td>The system clock on either the local or remote system is wrong.</td>
<td>This may cause the server or client to conclude that a credential has expired.</td>
<td>Check the system clocks on the local and remote system.</td>
</tr>
<tr>
<td>Your end-user certificate may have expired</td>
<td>Your end-user certificate may have expired</td>
<td>Use grid-cert-info to check your certificate's expiration date. If it has expired, follow your CA's procedures to get a new one.</td>
</tr>
<tr>
<td>The permissions may be wrong on your proxy file</td>
<td>If the permissions on your proxy file are too lax (for example, if others can read your proxy file), Globus Toolkit clients will not use that file to authenticate.</td>
<td>You can &quot;fix&quot; this problem by changing the permissions on the file or by destroying it (with grid-proxy-destroy) and creating a new one (with grid-proxy-init). <strong>Important:</strong> However, it is still possible that someone else has made a copy of that file during the time that the permissions were wrong. In that case, they will be able to impersonate you until the proxy file expires or your permissions or end-user certificate are revoked, whichever happens first.</td>
</tr>
<tr>
<td>The permissions may be wrong on your private key file</td>
<td>If the permissions on your end user certificate private key file are too lax (for example, if others can read the file), grid-proxy-init will refuse to create a proxy certificate.</td>
<td>You can &quot;fix&quot; this by changing the permissions on the private key file. <strong>Important:</strong> However, you will still have a much more serious problem: it is possible that someone has made a copy of your private key file. Although this file is encrypted, it is possible that someone will be able to decrypt the private key, at which point they will be able to impersonate you as long as your end user certificate is valid. You should contact your CA to have your end-user certificate revoked and get a new one.</td>
</tr>
<tr>
<td>The remote system may not trust your CA</td>
<td>The remote system may not trust your CA</td>
<td>Verify that the remote system is configured to trust the CA that issued your end-entity certificate. See Installing GT 4.2.0 for details.</td>
</tr>
<tr>
<td>You may not trust the remote system's CA</td>
<td>You may not trust the remote system's CA</td>
<td>Verify that your system is configured to trust the remote CA (or that your environment is set up to trust the remote CA). See Installing GT 4.2.0 for details.</td>
</tr>
<tr>
<td>There may be something wrong with the remote service's credentials</td>
<td>There may be something wrong with the remote service's credentials</td>
<td>It is sometimes difficult to distinguish between errors reported by the remote service regarding your credentials and errors reported by the client interface regarding the remote service's credentials. If you cannot find anything wrong with your credentials, check for the same conditions on the remote system (or ask a remote administrator to do so).</td>
</tr>
</tbody>
</table>
1.2. Some tools to validate certificate setup

1.2.1. Check that the user certificate is valid

openssl verify -CApath /etc/grid-security/certificates
    -purpose sslclient ~/.globus/usercert.pem

1.2.2. Connect to the server using s_client

openssl s_client -ssl3 -cert ~/.globus/usercert.pem -key
    ~/.globus/userkey.pem -CApath /etc/grid-security/certificates
    -connect <host:port>

Here <host:port> denotes the server and port you connect to.

If it prints an error and puts you back at the command prompt, then it typically means that the server has closed the connection, i.e. that the server was not happy with the client's certificate and verification. Check the SSL log on the server.

If the command "hangs" then it has actually opened a telnet style (but secure) socket, and you can "talk" to the server.

You should be able to scroll up and see the subject names of the server's verification chain:

depth=2 /DC=net/DC=ES/O=ESnet/OU=Certificate Authorities/CN=ESnet Root CA 1
verify return:1
depth=1 /DC=org/DC=DOEGrids/OU=Certificate Authorities/CN=DOEGrids CA 1
verify return:1
depth=0 /DC=org/DC=doegrids/OU=Services/CN=wiggum.mcs.anl.gov
verify return:1

In this case, there were no errors. Errors would give you an extra line next to the subject name of the certificate that caused the error.

1.2.3. Check that the server certificate is valid

Requires root login on server:

openssl verify -CApath /etc/grid-security/certificates -purpose sslserver
    /etc/grid-security/hostcert.pem
2. Error Messages For Java WS A&A
Table 7.2. Java WS A&A Errors

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Definition</th>
<th>Possible Solutions</th>
</tr>
</thead>
<tbody>
<tr>
<td>[JWSSEC-248] Secure container requires valid credentials</td>
<td>This error occurs when globus-start-container is run without any valid credentials. Either a proxy certificate or service/host certificate needs to be configured for the container to start up.</td>
<td>1. If you are not looking to start up a container that uses GSI Secure Transport, which is used by the container by default, use globus-start-container -nosec. You will be able to use insecure clients and services. However, this also implies that if you have not configured individual services with credentials, you will not be able to securely access the service.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2. If you are running a personal container, generate a proxy certificate with grid-proxy-init. If the proxy certificate is not in the default location, configure the container security descriptor as described in Configuring Container Security Descriptor.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3. If you want to use host certificates, configure the container security descriptor as described Configuring Credentials.</td>
</tr>
<tr>
<td>Failed to start container: Container failed to initialize</td>
<td>This error occurs if the file path to the container certificate/key configured are invalid.</td>
<td>1. The path to the container certificate and key are configured in $GLOBUS_LOCATION/etc/globus_wsrf_core/global_security_descriptor.xml. This file is loaded as described [here - fixme link]. Ensure that the path is correct.</td>
</tr>
<tr>
<td>[Caused by: [JWSSEC-250] Failed to load certificate/key file]</td>
<td></td>
<td>2. Refer to the &quot;Caused by: &quot; section for details on the specific element that is not correct.</td>
</tr>
<tr>
<td>Failed to start container: Container failed to initialize</td>
<td>This error occurs if container proxy file configured is invalid.</td>
<td>1. The path to the container proxy certificates are configured in $GLOBUS_LOCATION/etc/globus_wsrf_core/global_security_descriptor.xml. This file is loaded as described [here - fixme link]. Ensure that the path is correct.</td>
</tr>
<tr>
<td>[Caused by: [JWSSEC-249] Failed to load proxy file]</td>
<td></td>
<td>2. Refer to the &quot;Caused by: &quot; section for details on the specific element that is not correct.</td>
</tr>
<tr>
<td>Failed to start container: Container failed to initialize</td>
<td>This error occurs if the container security descriptor configured is invalid.</td>
<td>1. The container security descriptor should conform to the Container Security Descriptor Schema.</td>
</tr>
<tr>
<td>[Caused by: ...)]</td>
<td></td>
<td>2. Refer to the &quot;Caused by: &quot; section for details on the specific element that is not correct.</td>
</tr>
</tbody>
</table>

Glossary

G

grid map file
A file containing entries mapping certificate subjects to local user names. This file can also serve as a access control list for GSI enabled services and is typically found in `/etc/grid-security/grid-mapfile`. For more information see the Gridmap section here.

H

host credentials
The combination of a host certificate and its corresponding private key.

P

private key
The private part of a key pair. Depending on the type of certificate the key corresponds to it may typically be found in `$HOME/.globus/userkey.pem` (for user certificates), `/etc/grid-security/hostkey.pem` (for host certificates) or `/etc/grid-security/<service>/<service>key.pem` (for service certificates).

For more information on possible private key locations see this.

T

transport-level security
Uses transport-level security (TLS) mechanisms.
