Chapter 2. RSL Specification v1.1

This is a document to specify the existing RSL v1.0 implementation and interfaces, as they are provided in the GT 5.0.0 release. This document serves as a reference, and more introductory text.

The Globus Resource Specification Language (RSL) provides a common interchange language to describe resources. The various components of the Globus Resource Management architecture manipulate RSL strings to perform their management functions in cooperation with the other components in the system. The RSL provides the skeletal syntax used to compose complicated resource descriptions, and the various resource management components introduce specific ATTRIBUTE, VALUE > pairings into this common structure. Each attribute in a resource description serves as a parameter to control the behavior of one or more components in the resource management system.

1. RSL Syntax Overview

The core syntax of the RSL syntax is the relation. Relations associate an attribute name with a value, eg the relation executable=a.out provides the name of an executable in a resource request. There are two generative syntactic structures in the RSL that are used to build more complicated resource descriptions out of the basic relations: compound requests and value sequences. In addition, the RSL syntax includes a facility to both introduce and dereference string substitution variables.

The simplest form of compound request, utilized by all resource management components, is the conjunct-request. The conjunct-request expresses a conjunction of simple relations or compound requests (like a boolean AND). The most common conjunct-request in Globus RSL strings is the combination of multiple relations such as executable name, node count, executable arguments, and output files for a basic GRAM job request. Similarly, the core RSL syntax includes a disjunct-request form to represent disjunctive relations (like a boolean OR). Currently, however, no resource management component utilizes the disjunct-request form.

The last form of compound request is the multi-request. The multi-request expresses multiple parallel resources that make up a resource description. The multi-request form differs from the conjunction and disjunction in two ways: multi-requests introduce new variable scope, meaning variables defined in one clause of a multi-request are not visible to the other clauses, and multi-requests introduce a non-reducible hierarchy to the resource description. Whereas relations within a conjunct-request can be thought of as constraints on the resource being described, the subclauses of a multi-request are best thought of as individual resource descriptions that together constitute an abstract resource collection; the same attributes may be constrained in different ways in each subclause without causing a logical contradiction.

An example of a contradiction would be to constrain the executable attribute to be two conflicting values within a conjunction. Currently, however, no resource management component utilizes the disjunct-request form.

The simplest form of value in the RSL syntax is the string literal. When explicitly quoted, literals can contain any character, and many common literals that don't contain special characters can appear without quotes. Values can also be variable references, in which case the variable reference is in essence replaced with the string value defined for that variable. RSL descriptions can also express string-concatenation of values, especially useful to construct long strings out of several variable references. String concatenation is supported with both an explicit concatenation operator and implicit concatenation for many idiomatic constructions involving variable references and literals.

In addition to the simple value forms given above, the RSL syntax includes the value sequence to express ordered sets of values. The value sequence syntax is used primarily for defining variables and for providing the argument list for a program.
2. RSL Tokenization Overview

Each RSL string consists of a sequence of RSL tokens, whitespace, and comments. The RSL tokens are either special syntax or regular unquoted literals, where special syntax contains one or more of the following listed special characters and unquoted literals are made of sequences of characters excluding the special characters.

The complete set of special characters that cannot appear as part of an unquoted literal is:

- + (plus)
- & (ampersand)
- | (pipe)
- ( (left paren)
- ) (right paren)
- = (equal)
- < (left angle)
- > (right angle)
- ! (exclamation)
- " (double quote)
- ' (apostrophe)
- ^ (carat)
- # (pound)
- $ (dollar)

These characters can only be used for the special syntactic forms described in the section and in the section or as within quoted literals.

Quoted literals are introduced with the " (double quote) or ' (single quote/apostrophe) and consist of all the characters up to (but not including) the next solo double or single quote, respectively. To escape a quote character within a quoted literal, the appearance of the quote character twice in a row is converted to a single instance of the character and the literal continues until the next solo quote character. For any quoted literal, there is only one possible escape sequence, eg within a literal delimited by the single quote character only the single quote character uses the escape notation and the double quote character can appear without escape.

Quoted literals can also be introduced with an alternate user delimiter notation. User delimited literals are introduced with the ^ (carat) character followed immediately by a user-provided delimiter; the literal consists of all the characters after the user's delimiter up to (but not including) the next solo instance of the delimiter. The delimiter itself may be escaped within the literal by providing two instances in a row, just as the regular quote delimiters are escaped in regular quoted literals.

RSL string comments use a notation similar to comments in the C programming language. Comments are introduced by the prefix (* . Comments continue to the first terminating suffix *) and cannot be nested. Comments are stripped from the RSL string during processing and are syntactically equivalent to whitespace.
Example 2.1. Quoted Literal Examples

Assign the value Hello. Welcome to "The Grid" to the attribute `arguments`, using double-quote as the delimiter and the escaping sequence.

```plaintext
arguments = "Hello. Welcome to "The Grid""
```

Assign the value Hello. Welcome to "The Grid" to the attribute `arguments` using the single-quote delimiter.

```plaintext
arguments = 'Hello. Welcome to "The Grid"
```

Assign the value Hello. Welcome to "The Grid" to the attribute `arguments` using a user-defined quoting character `!`.

```plaintext
arguments = ^!Hello. Welcome to "The Grid"!
```

3. RSL Substitution Semantics

RSL strings can introduce and reference string variables. String substitution variables are defined in a special relation using the `rsl_substitution` attribute, and the definitions affect variable references made in the same conjunct-request (or disjunct-request), as well as references made within any multi-request nested inside one of the clauses of the conjunction (or disjunction). Each multi-request introduces a new variable scope for each subrequest, and variable definitions do not escape the closest enclosing scope.

Within any given scope, variable definitions are processed left-to-right in the resource description. Outermost scopes are processed before inner scopes, and the definitions in inner scopes augment the inherited definitions with new and/or updated variable definitions.

Variable definitions and variable references are processed in a single pass, with each definition updating the `environment` prior to processing the next definition. The value provided in a variable definition may include a reference to a previously-defined variable. References to variables that are not yet provided with definitions in the standard RSL variable processing order are replaced with an empty literal string.

4. RSL Attribute Summary

The RSL syntax is extensible because it defines structure without too many keywords. Each Globus resource management component introduces additional attributes to the set recognized by RSL-aware components, so it is difficult to provide a complete listing of attributes which might appear in a resource description. Resource management components are designed to utilize attributes they recognize and pass unrecognized relations through unchanged. This allows powerful compositions of different resource management functions.

The following listing summarizes the attribute names utilized by existing resource management components in the standard Globus release. Please see the individual component documentation for discussion of the attribute semantics.

4.1. GRAM5 Common RSL Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arguments</td>
<td>The command line arguments for the executable. Use quotes, if a space is required in a single argument.</td>
</tr>
<tr>
<td>count</td>
<td>The number of executions of the executable.</td>
</tr>
<tr>
<td>directory</td>
<td>Specifies the path of the directory the jobmanager will use as the default directory for the requested job.</td>
</tr>
</tbody>
</table>
dry_run
If dryrun = yes then the jobmanager will not submit the job for execution and will return success.

environment
The environment variables that will be defined for the executable in addition to default set that is given to the job by the jobmanager.

executable
The name of the executable file to run on the remote machine. If the value is a GASS URL, the file is transferred to the remote gass cache before executing the job and removed after the job has terminated.

file_clean_up
Specifies a list of files which will be removed after the job is completed.

file_stage_in
Specifies a list of ("remote URL" "local file") pairs which indicate files to be staged to the nodes which will run the job.

file_stage_in_shared
Specifies a list of ("remote URL" "local file") pairs which indicate files to be staged into the cache. A symlink from the cache to the "local file" path will be made.

file_stage_out
Specifies a list of ("local file" "remote URL") pairs which indicate files to be staged from the job to a GASS-compatible file server.

gass_cache
Specifies location to override the GASS cache location.

gram_my_job
Obsolete and ignored.

host_count
Only applies to clusters of SMP computers, such as newer IBM SP systems. Defines the number of nodes ("pizza boxes") to distribute the "count" processes across.

job_type
This specifies how the jobmanager should start the job. Possible values are single (even if the count > 1, only start 1 process or thread), multiple (start count processes or threads), mpi (use the appropriate method (e.g. mpirun) to start a program compiled with a vendor-provided MPI library. Program is started with count nodes), and condor (starts condor jobs in the "condor" universe.)

library_path
Specifies a list of paths to be appended to the system-specific library path environment variables.

max_cpu_time
Explicitly set the maximum cpu time for a single execution of the executable. The units is in minutes. The value will go through an atoi() conversion in order to get an integer. If the GRAM scheduler cannot set cputime, then an error will be returned.

max_memory
Explicitly set the maximum amount of memory for a single execution of the executable. The units is in Megabytes. The value will go through an atoi() conversion in order to get an integer. If the GRAM scheduler cannot set maxMemory, then an error will be returned.

max_time
The maximum walltime or cputime for a single execution of the executable. Walltime or cputime is selected by the GRAM scheduler being interfaced. The units is in minutes. The value will go through an atoi() conversion in order to get an integer.

max_wall_time
Explicitly set the maximum walltime for a single execution of the executable. The units is in minutes. The value will go through an atoi() conversion in order to get an integer. If the GRAM scheduler cannot set walltime, then an error will be returned.

min_memory
Explicitly set the minimum amount of memory for a single execution of the executable. The units is in Megabytes. The value will go through an atoi() conversion in order to
get an integer. If the GRAM scheduler cannot set minMemory, then an error will be returned.

**project**

Target the job to be allocated to a project account as defined by the scheduler at the defined (remote) resource.

**proxy_timeout**

Obsoleted and ignored. Now a job-manager-wide setting.

**queue**

Target the job to a queue (class) name as defined by the scheduler at the defined (remote) resource.

**remote_io_url**

Writes the given value (a URL base string) to a file, and adds the path to that file to the environment through the GLOBUS_REMOTE_IO_URL environment variable. If this is specified as part of a job restart RSL, the job manager will update the file’s contents. This is intended for jobs that want to access files via GASS, but the URL of the GASS server has changed due to a GASS server restart.

**restart**

Start a new job manager, but instead of submitting a new job, start managing an existing job. The job manager will search for the job state file created by the original job manager. If it finds the file and successfully reads it, it will become the new manager of the job, sending callbacks on status and streaming stdout/err if appropriate. It will fail if it detects that the old jobmanager is still alive (via a timestamp in the state file). If stdout or stderr was being streamed over the network, new stdout and stderr attributes can be specified in the restart RSL and the jobmanager will stream to the new locations (useful when output is going to a GASS server started by the client that’s listening on a dynamic port, and the client was restarted). The new job manager will return a new contact string that should be used to communicate with it. If a jobmanager is restarted multiple times, any of the previous contact strings can be given for the restart attribute.

**rsl_substitution**

Specifies a list of values which can be substituted into other rsl attributes’ values through the $(SUBSTITUTION) mechanism.

**save_state**

Causes the jobmanager to save it’s job state information to a persistent file on disk. If the job manager exits or is suspended, the client can later start up a new job manager which can continue monitoring the job.

**scratch_dir**

Specifies the location to create a scratch subdirectory in. A SCRATCH_DIRECTORY RSL substitution will be filled with the name of the directory which is created.

**stderr**

The name of the remote file to store the standard error from the job. If the value is a GASS URL, the standard error from the job is transferred dynamically during the execution of the job.

**stderr_position**

Specifies where in the file remote standard error streaming should be restarted from. Must be 0.

**stdin**

The name of the file to be used as standard input for the executable on the remote machine. If the value is a GASS URL, the file is transferred to the remote gass cache before executing the job and removed after the job has terminated.

**stdout**

The name of the remote file to store the standard output from the job. If the value is a GASS URL, the standard output from the job is transferred dynamically during the execution of the job.

**stdout_position**

Specifies where in the file remote output streaming should be restarted from. Must be 0.
Use a two-phase commit for job submission and completion. The job manager will respond to the initial job request with a WAITING_FOR_COMMIT error. It will then wait for a signal from the client before doing the actual job submission. The integer supplied is the number of seconds the job manager should wait before timing out. If the job manager times out before receiving the commit signal, or if a client issues a cancel signal, the job manager will clean up the job's files and exit, sending a callback with the job status as GLOBUSGRAM_PROTOCOL_JOB_STATE_FAILED. After the job manager sends a DONE or FAILED callback, it will wait for a commit signal from the client. If it receives one, it cleans up and exits as usual. If it times out and save_state was enabled, it will leave all of the job's files in place and exit (assuming the client is down and will attempt a job restart later). The timeout value can be extended via a signal. When one of the following errors occurs, the job manager does not delete the job state file when it exits: GLOBUSGRAM_PROTOCOL_ERROR_COMMIT_TIMED_OUT, GLOBUSGRAM_PROTOCOL_ERROR_TTL_EXPIRED, GLOBUSGRAM_PROTOCOL_ERROR_JM_STOPPED, GLOBUSGRAM_PROTOCOL_ERROR_USER_PROXY_EXPIRED. In these cases, it can not be restarted, so the job manager will not wait for the commit signal after sending the FAILED callback.

Verify that the job is running as this user.

5. Simple RSL Examples

The following are some simple example RSL strings to illustrate idiomatic usage with existing tools and to make concrete some of the more interesting cases of tokenization, concatenation, and variable semantics. These are meant to illustrate the use of the RSL notation without much regard for the specific details of a particular resource management component.

Typical GRAM5 resource descriptions contain at least a few relations in a conjunction:
**Example 2.2. GRAM5 Job Request Examples**

This example shows a conjunct request containing values that are unquoted literals and ordered sequences of a mix of quoted and unquoted literals.

```plaintext
(* this is a comment *)
& (executable = a.out (* <-- that is an unquoted literal *))
   (directory = /home/nobody )
   (arguments = arg1 "arg 2")
   (count = 1)
```

This example demonstrates RSL substitutions, which can be used to make sure a string is used consistently multiple times in a resource description:

```plaintext
& (rsl_substitution = (TOPDIR "/home/nobody")
   (DATADIR "/home/nobody/data")
   (EXECDIR "/home/nobody/bin")
   (executable = $(EXECDIR)/a.out
      (* ^-- implicit concatenation *))
   (directory = $(TOPDIR) )
   (arguments = $(DATADIR)/file1
      (* ^-- implicit concatenation *)
      $(DATADIR) # /file2
      (* ^-- explicit concatenation *)
      "$(FOO)"
      (* <-- a quoted literal *))
   (environment = (DATADIR $(DATADIR)))
   (count = 1)
```

Performing all variable substitution and removing comments yields an equivalent RSL string:

```plaintext
& (rsl_substitution = (TOPDIR "/home/nobody")
   (DATADIR "/home/nobody/data")
   (EXECDIR "/home/nobody/bin")
   (executable = "/home/nobody/bin/a.out"
      (directory = "/home/nobody"
      (arguments = "/home/nobody/data/file1"
         "/home/nobody/data/file2"
         "$\{FOO\}" )
      (environment = (DATADIR "/home/nobody/data")))
      (count = 1)
```

Note in the above variable-substitution example, the variable substitution definitions are not automatically made a part of the job's environment. And explicit environment attribute must be used to add environment variables for the job. Also note that the third value in the arguments clause is not a variable reference but only quoted literal that happens to contain one of the special characters.

### 6. RSL grammar and tokenization rules

The following is a modified BNF grammar for the Resource Specification Language. Lexical rules are provided for the implicit concatenation sequences in the form of conventional regular expressions; for the implicit-concat non-terminal rules, whitespace is not allowed between juxtaposed non-terminals. Grammar comments are provided in square
brackets in a column to the right of the productions, eg `[comment]` to help relate productions in the grammar to the terminology used in the above discussion.

Regular expressions are provided for the terminal class `string-literal` and for RSL comments. These regular expression make use of a common inverted character-class notation, as popularized by the various lex tools. Comments are syntactically equivalent to whitespace and can only appear where the comment prefix cannot be mistaken for the trailing part of a multi-character unquoted literal.

**RSL Grammar**

```plaintext
specification ::= relation
    | `+` spec-list
    | `&` spec-list
    | `|` spec-list

spec-list ::= `(specification ')` spec-list
    | `(specification ')`

relation ::= `rsl_substitution '=' binding-sequence`
    | `attribute op value-sequence`

binding-sequence ::= binding binding-sequence
    | binding

attribute ::= `string-literal simple-value ')'

value ::= `value-sequence '<'` value-sequence
    | `value-sequence '>'`

value-sequence ::= `value`
    | `value-sequence`
    | `value-sequence` `value`

simple-value ::= `simple-value '#' simple-value`
    | `implicit-concat`
    | `variable-reference`

variable-reference ::= `(string-literal)`

implicit-concat ::= `variable-reference`
    | `variable-reference unquoted-literal`

unquoted-literal ::= `unquoted-literal`
    | `unquoted-literal`

quoted-literal ::= `unquoted-literal`
    | `unquoted-literal`
    | `unquoted-literal`
    | `unquoted-literal`

```

/* relation */
/* multi-request */
/* conjunct-request */
/* disjunct-request */

/* Substitution variable definition */
/* Attribute binding relation */

/* String */
/* Concatenation */
/* Single-quote delimiter with escaping */
/* Double-quote delimiter with escaping */
/* User defined delimiter c with escaping */
/* Non-special characters */
/* Comment */
```
GRAM5 Commands
Name

globusrun -- Execute and manage jobs via GRAM

globusrun [-p | -parse]
   { -f RSL_FILENAME| -file RSL_FILENAME | RSL_SPECIFICATION }
globusrun [-n] [-no-interrupt]
   { -r RESOURCE_CONTACT| -resource RESOURCE_CONTACT }
   { -a | -authenticate-only }
globusrun [-n] [-no-interrupt]
   { -r RESOURCE_CONTACT | -resource RESOURCE_CONTACT }
   { -j | -jobmanager-version }
globusrun [-n] [-no-interrupt] { -k | -kill } {JOB_ID}
globusrun { -status } {JOB_ID}
   { -r RESOURCE_CONTACT | -resource RESOURCE_CONTACT }
   { -f RSL_FILENAME | -file RSL_FILENAME | RSL_SPECIFICATION }

Description

The globusrun program for submits and manages jobs run on a local or remote job host. The jobs are controlled by the globus-job-manager program which interfaces with a local resource manager that schedules and executes the job.

The globusrun program can be run in a number of different modes chosen by command-line options.

When -help, -usage, -version, or -versions command-line options are used, globusrun will print out diagnostic information and then exit.

When the -p or -parse command-line option is present, globusrun will verify the syntax of the RSL specification and then terminate. If the syntax is valid, globusrun will print out the string "RSL Parsed Successfully..." and exit with a zero exit code; otherwise, it will print an error message and terminate with a non-zero exit code.

When the -a or -authenticate-only command-line option is present, globusrun will verify that the service named by RESOURCE_CONTACT exists and the client’s credentials are granted permission to access that service. If authentication is successful, globusrun will display the string "GRAM Authentication test successful" and exit with a zero exit code; otherwise, it will print an explanation of the problem and will with a non-zero exit code.

When the -j or -jobmanager-version command-line option is present, globusrun will attempt to determine the software version that the service named by RESOURCE_CONTACT is running. If successful, it will display both the Toolkit version and the Job Manager package version and exit with a zero exit code; otherwise, it will print an explanation of the problem and will with a non-zero exit code.

When the -k or -kill command-line option is present, globusrun will attempt to terminate the job named by JOB_ID. If successful, globusrun will exit with zero; otherwise, it will display an explanation of the problem and exit with a non-zero exit code.

When the -y or -refresh-proxy command-line option is present, globusrun will attempt to delegate a new X.509 proxy to the job manager which is managing the job named by JOB_ID. If successful, globusrun will exit with zero; otherwise, it will display an explanation of the problem and exit with a non-zero exit code. This behavior can be modified by the -full-proxy or -D command-line options to enable full proxy delegation. The default is limited proxy delegation.
When the `-status` command-line option is present, `globusrun` will attempt to determine the current state of the job. If successful, the state will be printed to standard output and `globusrun` will exit with a zero exit code; otherwise, a description of the error will be displayed and it will exit with a non-zero exit code.

Otherwise, `globusrun` will submit the job to a GRAM service. By default, `globusrun` waits until the job has terminated or failed before exiting, displaying information about job state changes and at exit time, the job exit code if it is provided by the GRAM service.

The `globusrun` program can also function as a GASS file server to allow the `globus-job-manager` program to stage files to and from the machine on which `globusrun` is executed to the GRAM service node. This behavior is controlled by the `-s`, `-o`, and `-w` command-line options.

Jobs submitted by `globusrun` can be monitored interactively or detached. To have `globusrun` detach from the GRAM service after submitting the job, use the `-b` or `-F` command-line options.

## Options

The full set of options to `globusrun` consist of:

- `-help` Display a help message to standard error and exit.
- `-usage` Display a one-line usage summary to standard error and exit.
- `-version` Display the software version of `globusrun` to standard error and exit.
- `-versions` Display the software version of all modules used by `globusrun` (including DiRT information) to standard error and then exit.
- `-p`, `-parse` Do a parse check on the job specification and print diagnostics. If a parse error occurs, `globusrun` exits with a non-zero exit code.
- `-f RSL_FILENAME`, `-file RSL_FILENAME` Read job specification from the file named by `RSL_FILENAME`.
- `-n`, `-no-interrupt` Disable handling of the SIGINT signal, so that the interrupt character (typically `Control-C`) causes `globusrun` to terminate without canceling the job.
- `-r RESOURCE_CONTACT`, `-resource RESOURCE_CONTACT` Submit the request to the resource specified by `RESOURCE_CONTACT`. A resource may be specified in the following ways:
  - `HOST`
  - `HOST:PORT`
  - `HOST:PORT/SERVICE`
  - `HOST/SERVICE`
  - `HOST::SUBJECT`
  - `HOST:PORT:SUBJECT`
  - `HOST/SERVICE:SUBJECT`
• \textit{HOST/SERVICE:SUBJECT}

• \textit{HOST:PORT/SERVICE:SUBJECT}

If any of \textit{PORT}, \textit{SERVICE}, or \textit{SUBJECT} is omitted, the defaults of 2811, jobmanager, and host@HOST are used respectively.

\texttt{-j, -jobmanager-version} \par
Print the software version being run by the service running at \texttt{RESOURCE\_CONTACT}.

\texttt{-k JOB_ID, -kill JOB_ID} \par
Kill the job named by \texttt{JOB_ID}

\texttt{-D, -full-proxy} \par
Delegate a full impersonation proxy to the service. By default, a limited proxy is delegated when needed.

\texttt{-y, -refresh-proxy} \par
Delegate a new proxy to the service processing \texttt{JOB_ID}.

\texttt{-status} \par
Display the current status of the job named by \texttt{JOB_ID}.

\texttt{-q, -quiet} \par
Do not display job state change or exit code information.

\texttt{-o, -output-enable} \par
Start a GASS server within the \texttt{globusrun} application that allows access to its standard output and standard error streams only. Also, augment the \texttt{RSL\_SPECIFICATION} with a definition of the GLOBUSRUN\_GASS\_URL RSL substitution and add stdout and stderr clauses which redirect the output and error streams of the job to the output and error streams of the interactive \texttt{globusrun} command. If this is specified, then \texttt{globusrun} acts as though the \texttt{-q} were also specified.

\texttt{-s, -server} \par
Start a GASS server within the \texttt{globusrun} application that allows access to its standard output and standard error streams for writing and any file local to the \texttt{globusrun} invocation for reading. Also, augment the \texttt{RSL\_SPECIFICATION} with a definition of the GLOBUSRUN\_GASS\_URL RSL substitution and add stdout and stderr clauses which redirect the output and error streams of the job to the output and error streams of the interactive \texttt{globusrun} command. If this is specified, then \texttt{globusrun} acts as though the \texttt{-q} were also specified.

\texttt{-w, -write-allow} \par
Start a GASS server within the \texttt{globusrun} application that allows access to its standard output and standard error streams for writing and any file local to the the \texttt{globusrun} invocation for reading or writing. Also, augment the \texttt{RSL\_SPECIFICATION} with a definition of the GLOBUSRUN\_GASS\_URL RSL substitution and add stdout and stderr clauses which redirect the output and error streams of the job to the output and error streams of the interactive \texttt{globusrun} command. If this is specified, then \texttt{globusrun} acts as though the \texttt{-q} were also specified.

\texttt{-b, -batch} \par
Terminate after submitting the job to the GRAM service. The \texttt{globusrun} program will exit after the job hits any of the following states: PENDING, ACTIVE, FAILED, or DONE. The GASS-related options can be used to stage input files, but standard output, standard error, and file staging after the job completes will not be processed.

\texttt{-F, -fast-batch} \par
Terminate after submitting the job to the GRAM service. The \texttt{globusrun} program will exit after it receives a reply from the service. The \texttt{JOB\_ID} will be displayed to standard output before terminating so that the job can be checked with the
globusrun

-status command-line option or modified by the -refresh-proxy or -kill command-line options.

-d, --dryrun Submit the job with the dryrun attribute set to true. When this is done, the job manager will prepare to start the job but start short of submitting it to the service. This can be used to detect problems with the RSL_SPECIFICATION.

Environment

If the following variables affect the execution of globusrun

X509_USER_PROXY Path to proxy credential.

X509_CERT_DIR Path to trusted certificate directory.

Bugs

The globusrun program assumes any failure to contact the job means the job has terminated. In fact, this may be due to the globus-job-manager program exiting after all jobs it is managing have reached the DONE or FAILED states. In order to reliably detect job termination, the two-phase RSL attribute should be used.

Name

globus-job-cancel -- Cancel a GRAM batch job

globus-job-cancel [-f | -force] [-q | -quiet] JOBID

Description

The `globus-job-cancel` program cancels the job named by `JOBID`. Any cached files associated with the job will remain until `globus-job-clean` is executed for the job.

By default, `globus-job-cancel` prompts the user prior to canceling the job. This behavior can be overridden by specifying the `-f` or `-force` command-line options.

Options

The full set of options to `globus-job-cancel` are:

- `--help`, `-help` Display a help message to standard error and exit.
- `--usage` Display a usage message to standard output.
- `--version` Display the software version of the `globus-job-cancel` program to standard output.
- `--version` Display the software version of the `globus-job-cancel` program including DiRT information to standard output.
- `--force`, `-f` Do not prompt to confirm job cancel and clean-up.
- `--quiet`, `-q` Do not print diagnostics for successful cancel. Implies `-f`

ENVIRONMENT

If the following variables affect the execution of `globus-job-cancel`.

- `X509_USER_PROXY` Path to proxy credential.
- `X509_CERT_DIR` Path to trusted certificate directory.
Name

globus-job-clean -- Cancel and clean up a GRAM batch job

Description

The globus-job-clean program cancels the job named by JOBID if it is still running, and then removes any cached files on the GRAM service node related to that job. In order to do the file clean up, it submits a job which removes the cache files. By default this cleanup job is submitted to the default GRAM resource running on the same host as the job. This behavior can be controlled by specifying a resource manager contact string as the parameter to the -r or -resource option.

By default, globus-job-clean prompts the user prior to canceling the job. This behavior can be overridden by specifying the -f or -force command-line options.

Options

The full set of options to globus-job-clean are:

- help, -usage  Display a help message to standard error and exit.
- version  Display the software version of the globus-job-clean program to standard output.
- version  Display the software version of the globus-job-clean program including DiRT information to standard output.
- resource RESOURCE, -r RESOURCE  Submit the clean-up job to the resource named by RESOURCE instead of the default GRAM service on the same host as the job contact.
- force, -f  Do not prompt to confirm job cancel and clean-up.
- quiet, -q  Do not print diagnostics for succesful clean-up. Implies -f

ENVIRONMENT

If the following variables affect the execution of globus-job-clean.

X509_USER_PROXY  Path to proxy credential.
X509_CERT_DIR  Path to trusted certificate directory.
Name
globus-job-get-output -- Retrieve the output and error streams from a GRAM job

globus-job-get-output [-r RESOURCE ] [-resource RESOURCE ]
[-out | -err ] [ -t LINES ] [ -tail LINES ] [ -follow LINES ] [-f LINES ] JOBID

Description
The globus-job-get-output program retrieves the output and error streams of the job named by JOBID. By default, globus-job-get-output will retrieve all output and error data from the job and display them to its own output and error streams. Other behavior can be controlled by using command-line options. The data retrieval is implemented by submitting another job which simply displays the contents of the first job's output and error streams. By default this retrieval job is submitted to the default GRAM resource running on the same host as the job. This behavior can be controlled by specifying a particular resource manager contact string as the RESOURCE parameter to the -r or -resource option.

Options
The full set of options to globus-job-get-output are:

- help, -usage Display a help message to standard error and exit.
- version Display the software version of the globus-job-get-output program to standard output.
- version Display the software version of the globus-job-get-output program including DiRT information to standard output.
- resource RESOURCE, -r RESOURCE Submit the retrieval job to the resource named by RESOURCE instead of the default GRAM service on the same host as the job contact.
- out Retrieve only the standard output stream of the job. The default is to retrieve both standard output and standard error.
- err Retrieve only the standard error stream of the job. The default is to retrieve both standard output and standard error.
- tail LINES, -t LINES Print only the last LINES count lines of output from the data streams being retrieved. By default, the entire output and error file data is retrieved. This option can not be used along with the -f or -follow options.
- follow LINES, -f LINES Print the last LINES count lines of output from the data streams being retrieved and then wait until canceled, printing any subsequent job output that occurs. By default, the entire output and error file data is retrieved. This option can not be used along with the -t or -tail options.

ENVIRONMENT
If the following variables affect the execution of globus-job-get-output.

X509_USER_PROXY Path to proxy credential.
X509_CERT_DIR Path to trusted certificate directory.

BUGS

The -f and -follow don't work in GRAM5.
Name

globus-job-run -- Execute a job using GRAM

globus-job-run [-dumpsrsl] [-dryrun] [-verify]
[ -file ARGUMENT_FILE]
SERVICE_CONTACT
[ -np PROCESSES | -count PROCESSES ]
[ -m MAX_TIME | -maxtime MAX_TIME ]
[ -p PROJECT | -project PROJECT ]
[ -q QUEUE | -queue QUEUE ]
[ -d DIRECTORY | -directory DIRECTORY ] [ -env NAME=VALUE ]...
[-x RSL_CLAUSE]
[ -l | -s ] EXECUTABLE [ARGUMENT...]

Description

The globus-job-run program constructs a job description from its command-line options and then submits the job to the GRAM service running at SERVICE_CONTACT. The executable and arguments to the executable are provided on the command-line after all other options. Note that the -dumpsrsl, -dryrun, -verify, and -file command-line options must occur before the first non-option argument, the SERVICE_CONTACT.

The globus-job-run provides similar functionality to globusrun in that it allows interactive start-up of GRAM jobs. However, unlike globusrun, it uses command-line parameters to define the job instead of RSL expressions.

Options

The full set of options to globus-job-run are:

- **-help, -usage** Display a help message to standard error and exit.
- **-version** Display the software version of the globus-job-run program to standard output.
- **-version** Display the software version of the globus-job-run program including DiRT information to standard output.
- **-dumpsrsl** Translate the command-line options to globus-job-run into an RSL expression that can be used with tools such as globusrun.
- **-dryrun** Submit the job request to the GRAM service with the dryrun option enabled. When this option is used, the GRAM service prepares to execute the job but stops before submitting the job to the LRM. This can be used to diagnose some problems such as missing files.
- **-verify** Submit the job request to the GRAM service with the dryrun option enabled and then without it enabled if the dryrun is successful.
- **-file ARGUMENT_FILE** Read additional command-line options from ARGUMENT_FILE.
- **-np PROCESSES, -count PROCESSES** Start PROCESSES instances of the executable as a single job.
Schedule the job to run for a maximum of MAX_TIME minutes.

Request that the job use the allocation PROJECT when submitting the job to the LRM.

Request that the job be submitted to the LRM using the named QUEUE.

Run the job in the directory named by DIRECTORY. Input and output files will be interpreted relative to this directory. This directory must exist on the file system on the LRM-managed resource. If not specified, the job will run in the home directory of the user the job is running as.

Define an environment variable named by NAME with the value VALUE in the job environment. This option may be specified multiple times to define multiple environment variables.

Use the file named by STDIN_FILE as the standard input of the job. If the -l option is specified, then this file is interpreted to be on a file system local to the LRM. If the -s option is specified, then this file is interpreted to be on the file system where globus-job-run is being executed, and the file will be staged via GASS. If neither is specified, the local behavior is assumed.

Use the file named by STDOUT_FILE as the destination for the standard output of the job. If the -l option is specified, then this file is interpreted to be on a file system local to the LRM. If the -s option is specified, then this file is interpreted to be on the file system where globus-job-run is being executed, and the file will be staged via GASS. If neither is specified, the local behavior is assumed.

Use the file named by STDERR_FILE as the destination for the standard error of the job. If the -l option is specified, then this file is interpreted to be on a file system local to the LRM. If the -s option is specified, then this file is interpreted to be on the file system where globus-job-run is being executed, and the file will be staged via GASS. If neither is specified, the local behavior is assumed.

Add a set of custom RSL attributes described by RSL_CLAUSE to the job description. The clause must be an RSL conjunction and may contain one or more attributes. This can be used to include attributes which can not be defined by other command-line options of globus-job-run.

When included outside the context of -stdin, -stdout, or -stderr command-line options, -l option alters the interpretation of the executable path. If the -l option is specified, then the executable is interpreted to be on a file system local to the LRM.

When included outside the context of -stdin, -stdout, or -stderr command-line options, -s option alters the interpretation of the executable path. If the -s option is specified, then the executable is interpreted to be on the file system where globus-job-run is being executed, and the file will be staged via GASS. If neither is specified, the local behavior is assumed.

ENVIRONMENT

If the following variables affect the execution of globus-job-run.
X509_USER_PROXY Path to proxy credential.

X509_CERT_DIR Path to trusted certificate directory.

Name

globus-job-status -- Check the status of a GRAM5 job

globus-job-status JOBID

Description

The globus-job-status program checks the status of a GRAM job by sending a status request to the job manager contact for that job specified by the JOBID parameter. If successful, it will print the job status to standard output. The states supported by globus-job-status are:

PENDING The job has been submitted to the LRM but has not yet begun execution.
ACTIVE The job has begun execution.
FAILED The job has failed.
SUSPENDED The job is currently suspended by the LRM.
DONE The job has completed.
UNSUBMITTED The job has been accepted by GRAM, but not yet submitted to the LRM.
STAGE_IN The job has been accepted by GRAM and is currently staging files prior to being submitted to the LRM.
STAGE_OUT The job has completed execution and is currently staging files from the service node to other http, GASS, or GridFTP servers.

Options

The full set of options to globus-job-status are:

-help, -usage Display a help message to standard error and exit.
-version Display the software version of the globus-job-status program to standard output.
-versions Display the software version of the globus-job-status program including DiRT information to standard output.

ENVIRONMENT

If the following variables affect the execution of globus-job-status.

X509_USER_PROXY Path to proxy credential.
X509_CERT_DIR Path to trusted certificate directory.
Bugs

The `globus-job-status` program can not distinguish between the case of the job manager terminating for any reason and the job being in the DONE state.

globusrun(1)
Name

globus-job-submit -- Submit a batch job using GRAM

globus-job-submit [-dumprsl] [-dryrun] [-verify]
[-file ARGUMENT_FILE]
SERVICE_CONTACT
[-np PROCESSES] [-count PROCESSES]
[-m MAX_TIME] [-maxtime MAX_TIME]
[-p PROJECT] [-project PROJECT]
[-q QUEUE] [-queue QUEUE]
[-d DIRECTORY] [-directory DIRECTORY]
[env NAME=VALUE]...
[-x RSL_CLAUSE]
[-l | -s] EXECUTABLE [ARGUMENT...]

Description

The globus-job-submit program constructs a job description from its command-line options and then submits the job to the GRAM service running at SERVICE_CONTACT. The executable and arguments to the executable are provided on the command-line after all other options. Note that the -dumprsl, -dryrun, -verify, and -file command-line options must occur before the first non-option argument, the SERVICE_CONTACT.

The globus-job-submit provides similar functionality to globusrun in that it allows batch submission of GRAM jobs. However, unlike globusrun, it uses command-line parameters to define the job instead of RSL expressions.

To retrieve the output and error streams of the job, use the program globus-job-get-output. To reclaim resources used by the job by deleting cached files and job state, use the program globus-job-clean. To cancel a batch job submitted by globus-job-submit, use the program globus-job-cancel.

Options

The full set of options to globus-job-submit are:

- **-help, -usage**
  Display a help message to standard error and exit.

- **-version**
  Display the software version of the globus-job-submit program to standard output.

- **-versions**
  Display the software version of the globus-job-submit program including DiRT information to standard output.

- **-dumprsl**
  Translate the command-line options to globus-job-submit into an RSL expression that can be used with tools such as globusrun.

- **-dryrun**
  Submit the job request to the GRAM service with the dryrun option enabled. When this option is used, the GRAM service prepares to execute the job but stops before submitting the job to the LRM. This can be used to diagnose some problems such as missing files.

- **-verify**
  Submit the job request to the GRAM service with the dryrun option enabled and then without it enabled if the dryrun is successful.
-file ARGUMENT_FILE
Read additional command-line options from ARGUMENT_FILE.

-np PROCESSES,-count PROCESSES
Start PROCESSES instances of the executable as a single job.

-m MAX_TIME,-maxtime MAX_TIME
Schedule the job to run for a maximum of MAX_TIME minutes.

-p PROJECT,-project PROJECT
Request that the job use the allocation PROJECT when submitting the job to the LRM.

-q QUEUE,-queue QUEUE
Request that the job be submitted to the LRM using the named QUEUE.

-d DIRECTORY,-directory DIRECTORY
Run the job in the directory named by DIRECTORY. Input and output files will be interpreted relative to this directory. This directory must exist on the file system on the LRM-managed resource. If not specified, the job will run in the home directory of the user the job is running as.

-env NAME=VALUE
Define an environment variable named by NAME with the value VALUE in the job environment. This option may be specified multiple times to define multiple environment variables.

-stdin [-l | -s] STDIN_FILE
Use the file named by STDIN_FILE as the standard input of the job. If the -l option is specified, then this file is interpreted to be on a file system local to the LRM. If the -s option is specified, then this file is interpreted to be on the file system where globus-job-submit is being executed, and the file will be staged via GASS. If neither is specified, the local behavior is assumed.

-stdout [-l | -s] STDOUT_FILE
Use the file named by STDOUT_FILE as the destination for the standard output of the job. If the -l option is specified, then this file is interpreted to be on a file system local to the LRM. If the -s option is specified, then this file is interpreted to be on the file system where globus-job-submit is being executed, and the file will be staged via GASS. If neither is specified, the local behavior is assumed.

-stderr [-l | -s] STDERR_FILE
Use the file named by STDERR_FILE as the destination for the standard error of the job. If the -l option is specified, then this file is interpreted to be on a file system local to the LRM. If the -s option is specified, then this file is interpreted to be on the file system where globus-job-submit is being executed, and the file will be staged via GASS. If neither is specified, the local behavior is assumed.

-x RSL_CLAUSE
Add a set of custom RSL attributes described by RSL_CLAUSE to the job description. The clause must be an RSL conjunction and may contain one or more attributes. This can be used to include attributes which can not be defined by other command-line options of globus-job-submit.

-l
When included outside the context of -stdin, -stdout, or -stderr command-line options, -l option alters the interpretation of the executable path. If the -l option is specified, then the executable is interpreted to be on a file system local to the LRM.

-s
When included outside the context of -stdin, -stdout, or -stderr command-line options, -s option alters the interpretation of the executable path. If the -s option is specified, then the executable is interpreted to be on the file system where globus-job-submit is being executed, and the file will be staged via GASS. If neither is specified, the local behavior is assumed.
system where `globus-job-run` is being executed, and the file will be staged via GASS. If neither is specified, the local behavior is assumed.

**ENVIRONMENT**

If the following variables affect the execution of `globus-job-submit`.

- `X509_USER_PROXY` Path to proxy credential.
- `X509_CERT_DIR` Path to trusted certificate directory.

Name

globus-personal-gatekeeper -- Manage a user's personal gatekeeper daemon

[-log [=DIRECTORY]] [-seg] [-acctfile ACCOUNTING_FILE]
globus-personal-gatekeeper [-killall] [-kill]

Description

The **globus-personal-gatekeeper** command is a utility which manages a gatekeeper and job manager service for a single user. Depending on the command-line arguments it will operate in one of several modes. In the first set of arguments indicated in the synopsis, the program provides information about the **globus-personal-gatekeeper** command or about instances of the **globus-personal-gatekeeper** that are running currently. The second set of arguments indicated in the synopsis provide control over starting a new **globus-personal-gatekeeper** instance. The final set of arguments provide control for terminating one or more **globus-personal-gatekeeper** instances.

The **-start** mode will create a new subdirectory of $HOME/.globus and write the configuration files needed to start a **globus-gatekeeper** daemon which will invoke the **globus-job-manager** service when new authenticated connections are made to its service port. The **globus-personal-gatekeeper** then exits, printing the contact string for the new gatekeeper prefixed by GRAM contact: to standard output. In addition to the arguments described above, any arguments described in **globus-job-manager**(8) can be appended to the command-line and will be added to the job manager configuration for the service started by the **globus-gatekeeper**.

The new **globus-gatekeeper** will continue to run in the background until killed by invoking **globus-personal-gatekeeper** with the **-kill** or **-killall** argument. When killed, it will kill the **globus-gatekeeper** and **globus-job-manager** processes, remove state files and configuration data, and then exit. Jobs which are running when the personal gatekeeper is killed will continue to run, but their job directory will be destroyed so they may fail in the LRM.

The full set of command-line options to **globus-personal-gatekeeper** consists of:

- **-help, -usage** Print command-line option summary and exit
- **-version** Print software version
- **-versions** Print software version including DiRT information
- **-list** Print a list of all currently running personal gatekeepers. These entries will be printed one per line.
- **-directory CONTACT** Print the configuration directory for the personal gatekeeper with the contact string **CONTACT**.
- **-debug** Print additional debugging information when starting a personal gatekeeper. This option is ignored in other modes.
- **-start** Start a new personal gatekeeper process.
- **-jmtype LRM** Use **LRM** as the local resource manager interface. If not provided when starting a personal gatekeeper, the job manager will use the default **fork** LRM.
- **-auditdir AUDIT_DIRECTORY** Write audit report files to **AUDIT_DIRECTORY**. If not provided, the job manager will not write any audit files.
-port PORT

Listen for gatekeeper TCP/IP connections on the port PORT. If not provided, the gatekeeper will let the operating system choose.

-log[=DIRECTORY]

Write job manager log files to DIRECTORY. If DIRECTORY is omitted, the default of $HOME will be used. If this option is not present, the job manager will not write any log files.

-seg

Try to use the SEG mechanism to receive job state change information, instead of polling for these. These require either the system administrator or the user to run an instance of the globus-job-manager-event-generator program for the LRM specified by the -jmtype option.

-acctfile ACCOUNTING_FILE

Write gatekeeper accounting entries to ACCOUNTING_FILE. If not provided, no accounting records are written.

Examples

This example shows the output when starting a new personal gatekeeper which will schedule jobs via the lsf LRM, with debugging enabled.

% globus-personal-gatekeeper -start -jmtype lsf

verifying setup...
done.
GRAM contact: personal-grid.example.org:57846:/DC=org/DC=example/CN=Joe User

This example shows the output when listing the current active personal gatekeepers.

% globus-personal-gatekeeper -list

personal-grid.example.org:57846:/DC=org/DC=example/CN=Joe User

This example shows the output when querying the configuration directory for the above personal gatekeeper.

% globus-personal-gatekeeper -directory "personal-grid.example.org:57846:/DC=org/DC=example/CN=Joe User"

/home/juser/.globus/.personal-gatekeeper.personal-grid.example.org.1337

% globus-personal-gatekeeper -kill "personal-grid.example.org:57846:/DC=org/DC=example/CN=Joe User"

killing gatekeeper: "personal-grid.example.org:57846:/DC=org/DC=example/CN=Joe User"

Name

globus-gram-audit -- Load GRAM4 and GRAM5 audit records into a database

globus-gram-audit [--conf CONFIG_FILE] [--check] [--delete] [--audit-directory AUDITDIR]

Description

The globus-gram-audit program loads audit records to an SQL-based database. It reads $GLOBUS_LOCATION/etc/globus-job-manager.conf by default to determine the audit directory and then uploads all files in that directory that contain valid audit records to the database configured by the globus_gram_job_manager_auditing_setup_scripts package. If the upload completes successfully, the audit files will be removed.

The full set of command-line options to globus-gram-audit consist of:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--conf CONFIG_FILE</td>
<td>Use CONFIG_FILE instead of the default from the configuration file for audit database configuration.</td>
</tr>
<tr>
<td>--check</td>
<td>Check whether the insertion of a record was successful by querying the database after inserting the records. This is used in tests.</td>
</tr>
<tr>
<td>--delete</td>
<td>Delete audit records from the database right after inserting them. This is used in tests to avoid filling the database with test records.</td>
</tr>
<tr>
<td>--audit-directory DIR</td>
<td>Look for audit records in DIR, instead of looking in the directory specified in the job manager configuration. This is used in tests to control which records are loaded to the database and then deleted.</td>
</tr>
<tr>
<td>--query SQL</td>
<td>Perform the given SQL query on the audit database. This uses the database information from the configuration file to determine how to contact the database.</td>
</tr>
</tbody>
</table>

FILES

The globus-gram-audit uses the following files (paths relative to $GLOBUS_LOCATION).

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>etc/globus-gram-job-manager.conf</td>
<td>GRAM5 job manager configuration. It includes the default path to the audit directory</td>
</tr>
<tr>
<td>etc/globus-gram-audit.conf</td>
<td>Audit configuration. It includes the information needed to contact the audit database.</td>
</tr>
</tbody>
</table>

globus-gatekeeper -- Authorize and execute a grid service on behalf of a user

globus-gatekeeper [-help]
[-conf \textit{PARAMETER\_FILE}]
[-test] [-d] [-debug]
{ -inetd \,-f }
[-p \textit{PORT} | -port \textit{PORT}]
[-home \textit{PATH} | -d \textit{LOGFILE} | -logfile \textit{LOGFILE}]
[-acctfile \textit{ACCTFILE}]
[-e \textit{LIBEXECDIR}]
[-launch_method \{ fork\_and\_exit | fork\_and\_wait | dont\_fork \}]
[-grid\_services \textit{SERVICEDIR}]
[-globusid \textit{GLOBUSID}]
[-gridmap \textit{GRIDMAP}]
[-x509\_cert\_dir \textit{TRUSTED\_CERT\_DIR}]
[-x509\_cert\_file \textit{TRUSTED\_CERT\_FILE}]
[-x509\_user\_cert \textit{CERT\_PATH}]
[-x509\_user\_key \textit{KEY\_PATH}]
[-x509\_user\_proxy \textit{PROXY\_PATH}]
[-k]
[-globus\_kmap \textit{KMAP}]

Description

The \textit{globus-gatekeeper} program is a meta-server similar to \textit{inetd} or \textit{xinetd} that starts other services after authenticating the TCP connection using GSSAPI.

The most common use for the \textit{globus-gatekeeper} program is to start instances of the \textit{globus-job-manager(8)} service. A single \textit{globus-gatekeeper} deployment can handle multiple different service configurations by having entries in the grid-services directory.

Typically, users interact with the \textit{globus-gatekeeper} program via client applications such as \textit{globusrun(1)}, \textit{globus\_job\_submit}, or tools such as CoG jglobus or Condor-G.

The full set of command-line options to \textit{globus-gatekeeper} consists of:

- **-help**
  Display a help message to standard error and exit

- **-conf \textit{PARAMETER\_FILE}**
  Load configuration parameters from \textit{PARAMETER\_FILE}. The parameters in that file are treated as additional command-line options.

- **-test**
  Parse the configuration file and print out the POSIX user id of the \textit{globus-gatekeeper} process, service home directory, service execution directory, and X.509 subject name and then exits.

- **-d, -debug**
  Run the \textit{globus-gatekeeper} process in the foreground.

- **-inetd**
  Flag to indicate that the \textit{globus-gatekeeper} process was started via \textit{inetd} or a similar super-server. If this flag is set and the \textit{globus-gatekeeper} was not started via inetd, a warning will be printed in the gatekeeper log.
-f Flag to indicate that the `globus-gatekeeper` process should run in the foreground. This flag has no effect when the `globus-gatekeeper` is started via inetd.

-p PORT, -port PORT Listen for connections on the TCP/IP port `PORT`. This option has no effect if the `globus-gatekeeper` is started via inetd or a similar service. If not specified and the gatekeeper is running as root, the default of 754 is used. Otherwise, the gatekeeper defaults to an ephemeral port.

-home PATH Sets the gatekeeper deployment directory to `PATH`. This is used to interpret relative paths for accounting files, libexecdir, certificate paths, and also to set the `GLOBUS_LOCATION` environment variable in the service environment. If not specified, the gatekeeper uses its working directory.

-l LOGFILE, -logfile LOGFILE Write status log entries to `LOGFILE`.

-acctfile ACCTFILE Set the path to write accounting records to `ACCTFILE`. If not set, no accounting records will be written.

-e LIBEXECDIR Look for service executables in `LIBEXECDIR`. If not specified, the default of `HOME/libexec` is used.

-launch_method fork_and_exit | fork_and_wait | dont_fork Determine how to launch services. The method may be either `fork_and_exit` (the service runs completely independently of the gatekeeper, which exits after creating the new service process), `fork_and_wait` (the service is run in a separate process from the gatekeeper but the gatekeeper does not exit until the service terminates), or `dont_fork`, where the gatekeeper process becomes the service process via the `exec()` system call.

-grid_services SERVICEDIR Look for service descriptions in `SERVICEDIR`. If this is a relative path, it is interpreted relative to the `HOME` value. If this is not specified, the default of `HOME/etc/grid-services` is used.

-globusid GLOBUSID Sets the `GLOBUSID` environment variable to `GLOBUSID`. This variable is used to construct the gatekeeper contact string if it can not be parsed from the service credential.

-gridmap GRIDMAP Use the file at `GRIDMAP` to map GSSAPI names to POSIX user names. If not specified, the default of `HOME/etc/grid-mapfile` is used.

-x509_cert_dir TRUSTED_CERT_DIR Use the directory `TRUSTED_CERT_DIR` to locate trusted CA X.509 certificates. The gatekeeper sets the environment variable `X509_CERT_DIR` to this value.

-x509_cert_file TRUSTED_CERT_FILE OBSOLETE GSI OPTION

-x509_user_cert CERT_PATH Read the service X.509 certificate from `CERT_PATH`. The gatekeeper sets the `X509_USER_CERT` environment variable to this value.

-x509_user_key KEY_PATH Read the private key for the service from `KEY_PATH`. The gatekeeper sets the `X509_USER_KEY` environment variable to this value.

-x509_user_proxy PROXY_PATH Read the X.509 proxy certificate from `PROXY_PATH`. The gatekeeper sets the `X509_USER_PROXY` environment variable to this value.

-k Assume authentication with Kerberos 5 GSSAPI instead of X.509 GSSAPI.
-globuskmap KMAP  Assume authentication with Kerberos 5 GSSAPI instead of X.509 GSSAPI and use KMAP as the path to the kerberos principal to POSIX user mapping file.

ENVIRONMENT

If the following variables affect the execution of globus-gatekeeper

X509_CERT_DIR  Directory containing X.509 trust anchors and signing policy files.
X509_USER_PROXY  Path to file containing an X.509 proxy.
X509_USER_CERT  Path to file containing an X.509 user certificate.
X509_USER_KEY  Path to file containing an X.509 user key.

Files

$GLOBUS_LOCATION/etc/globus-gatekeeper.conf  Default path to gatekeeper configuration file.

$GLOBUS_LOCATION/etc/grid-services/SERVICENAME.conf  Service configuration for SERVICENAME.

Name

globus-job-manager -- Execute and monitor jobs

Description

The globus-job-manager program is a service which starts and controls GRAM jobs which are executed by a local resource management system, such as LSF or Condor. The globus-job-manager program is typically started by the globus-gatekeeper program and not directly by a user. It runs until all jobs it is managing have terminated or its delegated credentials have expired.

Typically, users interact with the globus-job-manager program via client applications such as globusrun, globus-job-submit, or tools such as CoG jglobus or Condor-G.

The full set of command-line options to globus-job-manager consists of:

- **-help**: Display a help message to standard error and exit
- **-type LRM**: Execute jobs using the local resource manager named LRM.
- **-conf CONFIG_PATH**: Read additional command-line arguments from the file CONFIG_PATH. If present, this must be the first command-line argument to the globus-job-manager program.
- **-globus-host-manufacturer MANUFACTURER**: Indicate the manufacturer of the system which the jobs will execute on. This parameter sets the value of the $ (GLOBUS_HOST_MANUFACTURER) RSL substitution to MANUFACTURER
- **-globus-host-cputype CPU_TYPE**: Indicate the CPU type of the system which the jobs will execute on. This parameter sets the value of the $ (GLOBUS_HOST_CPUTYPE) RSL substitution to CPU_TYPE
- **-globus-host-osname OSNAME**: Indicate the operating system type of the system which the jobs will execute on. This parameter sets the value of the $ (GLOBUS_HOST_OSNAME) RSL substitution to OSNAME
- **-globus-host-osversion OSVERSION**: Indicate the operating system version of the system which the jobs will execute on. This parameter sets the value of the $ (GLOBUS_HOST_OSVERSION) RSL substitution to OSVERSION
- **-globus-gatekeeper-host HOST**: Indicate the host name of the machine which the job was submitted to. This parameter sets the value of the $ (GLOBUS_GATEKEEPER_HOST) RSL substitution to HOST
-globus-gatekeeper-port PORT
Indicate the TCP port number of gatekeeper to which jobs are submitted to. This parameter sets the value of the $(GLOBUS_GATEKEEPER_PORT) RSL substitution to PORT.

-globus-gatekeeper-subject SUBJECT
Indicate the X.509 identity of the gatekeeper to which jobs are submitted to. This parameter sets the value of the $(GLOBUS_GATEKEEPER_SUBJECT) RSL substitution to SUBJECT.

-home GLOBUS_LOCATION
Indicate the path where the Globus Toolkit(r) is installed on the service node. This is used by the job manager to locate its support and configuration files.

-target-globus-location TARGET_GLOBUS_LOCATION
Indicate the path where the Globus Toolkit(r) is installed on the execution host. If this is omitted, the value specified as a parameter to -home is used. This parameter sets the value of the $(GLOBUS_LOCATION) RSL substitution to TARGET_GLOBUS_LOCATION.

-history HISTORY_DIRECTORY
Configure the job manager to write job history files to HISTORY_DIRECTORY. These files are described in the FILES section below.

-scratch-dir-base SCRATCH_DIRECTORY
Configure the job manager to use SCRATCH_DIRECTORY as the default scratch directory root if a relative path is specified in the job RSL's scratch_dir attribute.

-enable-syslog
Configure the job manager to write log messages via syslog. Logging is further controlled by the argument to the -log-levels parameter described below.

-stdio-log LOG_DIRECTORY
Configure the job manager to write log messages to files in the LOG_DIRECTORY directory. Files will be named LOG_DIRECTORY/gram_YYYYMM-DD.log. Logging is further controlled by the argument to the -log-levels parameter described below. The LOG_DIRECTORY value can include variables derived from the job manager environment using the same syntax as RSL substitutions. For example, -stdio-log $(HOME) would cause each user's logs to be stored in their individual home directories.

-log-levels LEVELS
Configure the job manager to write log messages of certain levels to syslog and/or log files. The available log levels are FATAL, ERROR, WARN, INFO, DEBUG, and TRACE. Multiple values can be combined with the | character. The default value of logging when enabled is FATAL|ERROR.

-state-file-dir STATE_DIRECTORY
Configure the job manager to write state files to STATE_DIRECTORY. If not specified, the job manager uses the default of $GLOBUS_LOCATION/tmp/gram_job_state/. This directory must be writable by all users and be on a file system which supports POSIX advisory file locks.

-globus-tcp-port-range PORT_RANGE
Configure the job manager to restrict its TCP/IP communication to use ports in the range described by PORT_RANGE. This value is also made available in the job environment via the GLOBUS_TCP_PORT_RANGE environment variable.

-x509-cert-dir TRUSTED_CERTIFICATE_DIRECTORY
Configure the job manager to search TRUSTED_CERTIFICATE_DIRECTORY for its list of trusted CA certificates and their signing policies. This value is also made available in the job environment via the X509_CERT_DIR environment variable.
-cache-location
GASS_CACHE_DIRECTORY
Configure the job manager to use the path GASSCACHE_DIRECTORY for its temporary GASS-cache files. This value is also made available in the job environment via the GLOBUSGASSCACHE_DEFAULT environment variable.

-k
Configure the job manager to assume it is using Kerberos for authentication instead of X.509 certificates. This disables some certificate-specific processing in the job manager.

-extra-envvars
VAR=VAL,...
Configure the job manager to define a set of environment variables in the job environment beyond those defined in the base job environment. The format of the parameter to this argument is a comma-separated sequence of VAR=VAL pairs, where VAR is the variable name and VAL is the variables value.

-seg-module SEG_MODULE
Configure the job manager to use the schedule event generator module named by SEG_MODULE to detect job state changes events from the local resource manager, in place of the less efficient polling operations used in GT2. To use this, one instance of the globus-job-manager-event-generator must be running to process events for the LRM into a generic format that the job manager can parse.

-audit-directory
AUDIT_DIRECTORY
Configure the job manager to write audit records to the directory named by AUDIT_DIRECTORY. This records can be loaded into a database using the globus-gram-audit program.

-globus-toolkit-version
TOOLKIT_VERSION
Configure the job manager to use TOOLKIT_VERSION as the version for audit and usage stats records.

-service-tag SERVICE_TAG
Configure the job manager to use SERVICE_TAG as a unique identifier to allow multiple GRAM instances to use the same job state directories without interfering with each other's jobs. If not set, the value untagged will be used.

-disable-streaming
Configure the job manager to disable file streaming. This is propagated to the LRM script interface but has no effect in GRAM5.

-disable-usagerequests
Disable sending of any usage stats data, even if -usagerequests-target is present in the configuration.

-usagerequests-target TARGET
Send usage packets to a data collection service for analysis. The TARGET string consists of a comma-separated list of HOST:PORT combinations, each containing an optional list of data to send. See Usage Stats Packets for more information about the tags. Special tag strings of all (which enables all tags) and default may be used, or a sequence of characters for the various tags.

-condor-arch ARCH
Set the architecture specification for condor jobs to be ARCH in job classified ads generated by the GRAM5 condor LRM script. This is required for the condor LRM but ignored for all others.

-condor-os OS
Set the operating system specification for condor jobs to be OS in job classified ads generated by the GRAM5 condor LRM script. This is required for the condor LRM but ignored for all others.

Name

globus-job-manager-event-generator -- Create LRM-independent SEG files for the job manager to use

Description

The globus-job-manager-event-generator program is a utility which uses LRM-specific SEG parsers to generate a LRM-independent log file that a job manager instance can use to process job status change events. This program runs independently of all globus-job-manager instances so that only one process needs to deal with the LRM interface. The globus-job-manager-event-generator program can be run as a privileged user if required to interface with the LRM.

In order for globus-job-manager-event-generator to handle events for a particular LRM, the globus_scheduler_event_generator_job_manager_setup setup package must be configured after the LRM-specific setup package has been run. This can be forced by gpt-postinstall-force or running the command cd $GLOBUS_LOCATION/setup/globus; ./setup-seg-job-manager.pl.

The full set of command-line options to globus-job-manager-event-generator consists of:

- **-help**     Print command-line option summary and exit.
- **-scheduler LRM**     Process events for the local resource manager named by LRM.
- **-background**     Run globus-job-manager-event-generator as a background process. It will fork a new process, print out its process ID and then the original process will terminate.
- **-pidfile PIDPATH**     Write the process ID of an instance of globus-job-manager-event-generator to the file named by PIDPATH. This file can be used to kill or monitor the globus-job-manager-event-generator process.

Files

globus-job-manager-seg.conf     Configuration file for globus-job-manager-event-generator. Each line consists of a string of the form LRM_log_path=PATH, which indicates the directory containing LRM-independent format SEG log files for the LRM. This file is created by the running the globus_scheduler_event_generator_job_manager_setup setup package.

globus-scheduler-event-generator(8), globus-job-manager(8)
Name

globus-fork-starter -- Start and monitor a fork job

globus-fork-starter

Description

The globus-fork-starter program is executes jobs specified on its standard input stream, recording the job state changes to a file defined in the $GLOBUS_LOCATION/etc/globus-fork.conf configuration file. It runs until its standard input stream is closed and all jobs it is managing have terminated. The log generated by this program can be used by the SEG to provide job state changes and exit codes to the GRAM service. The globus-fork-starter program is typically started by the fork GRAM module.

The globus-fork-starter program expects its input to be a series of task definitions, separated by the newline character, each representing a separate job. Each task definition contains a number of fields, separated by the colon character. The first field is always the literal string 100 indicating the message format, the second field is a unique job tag that will be distinguish the reply from this program when multiple jobs are submitted. The rest of fields contain attribute bindings. The supported attributes are:

- directory: Working directory of the job
- environment: Comma-separated list of strings defining environment variables. The form of these strings is var=value
- count: Number of processes to start
- executable: Full path to the executable to run
- arguments: Comma-separated list of command-line arguments for the job
- stdin: Full path to a file containing the input of the job
- stdout: Full path to a file to write the output of the job to
- stderr: Full path to a file to write the error stream of the job

Within each field, the following characters may be escaped by preceding them with the backslash character:

- backslash (\)
- semicolon (;)
- comma (,)
- equal (=)

Additionally, newline can be represented within a field by using the escape sequence \n.

For each job the globus-fork-starter processes, it replies by writing a single line to standard output. The replies again consist of a number of fields separated by the semicolon character.

For a successful job start, the first field of the reply is the literal 101, the second field is the tag from the input, and the third field is a comma-separated list of SEG job identifiers which consist the concatenation of a UUID and a process id. The globus-fork-starter program will write state changes to the SEG log using these job identifiers.
For a failure, the first field of the reply is the literal 102, the second field is the tag from the input, the third field is the integer representation of a GRAM error code, and the fourth field is an string explaining the error.

**ENVIRONMENT**

If the following variables affect the execution of globus-fork-starter

**GLOBUS_LOCATION** Path to Globus Toolkit installation. This is used to locate the globus-fork.conf configuration file.

**Files**

$GLOBUS_LOCATION/etc/globus-fork.conf Path to fork SEG configuration file.

bus-fork.conf
Chapter 3. Job description

Jobs are described in GRAM5's job description language. For detailed schema information see the GRAM5 RSL documentation. For more information and examples please check the Globusrun section in the GRAM5 Users's guide.
Chapter 4. Semantics and syntax of protocols

1. GRAM5 Protocol

The GRAM Protocol is used to handle communication between the Gatekeeper, Job Manager, and GRAM Clients. The protocol is based on a subset of the HTTP/1.1 protocol, with a small set of message types and responses sent as the body of the HTTP requests and responses. This document describes GRAM Protocol version 2 as used by GRAM5. This is compatible with the GRAM Protocol parsers in GRAM2 with extensions.

1.1. Framing

GRAM messages are framed in HTTP/1.1 messages. However, only a small subset of the HTTP specification is used or understood by the GRAM system. All GRAM requests are HTTP POST messages. Only the following HTTP headers are understood:

- Host
- Content-Type (set to "application/x-globus-gram" in all cases)
- Content-Length
- Connection (set to "close" in all HTTP responses)

Only the following status codes are supported in response's HTTP Status-Line:

- 200 OK
- 403 Forbidden
- 404 Not Found
- 500 Internal Server Error
- 400 Bad Request

1.2. Message Format

All messages use the carriage return (ASCII value 13) followed by line feed (ASCII value 10) sequence to delimit lines. In all cases, a blank line separates the HTTP header from the message body. All application/x-globus-gram message bodies consist of attribute names followed by a colon, a space, and then the value of the attribute. When the value may contain a newline or double-quote character, a special escaping rule is used to encapsulate the complete string. This encapsulation consists of surrounding the string with double-quotes, and escaping all double-quote and backslash characters within the string with a backslash. All other characters are sent without modification. For example, the string

\[ rsl: &\{( executable = "/bin/echo" ) \( arguments = "hello" )\]
rsl: "&{ executable = "bin/echo" }
    (arguments = "hello")"

In GRAM5, protocol extensions are supported in the status update messages. These extensions are implemented as extra attribute names after all of the attributes defined in the messages below. Older GRAM protocol parsers will ignore those extensions that occur after the attributes in the messages defined below. In GRAM5, the following extensions are used:

**exit-code**

Job exit code. Sent in job state callbacks and in job status replies when the job completes.

**gt3-failure-type**

Failure detail type for staging errors. Sent in job state callbacks and in job status replies when a job fails.

**gt3-failure-message**

Failure detail message for more context for errors. Sent in job state callbacks and in job status replies when a job fails.

**gt3-failure-source**

Failure detail message for the source of a failed file transfer. Sent in job state callbacks and in job status replies when a job fails.

**gt3-failure-destination**

Failure detail message for the destination of a failed file transfer. Sent in job state callbacks and in job status replies when a job fails.

**version**

Job manager package version. Sent in all messages from the job manager.

**toolkit-version**

Toolkit release that the job manager is running. Sent in all messages from the job manager.

This is the only form of quoting which application/x-globus-gram messages support. Use of `% HEX HEX` escapes (such as seen in URL encodings) is not meaningful for this protocol.

### 1.3. Message Types

#### 1.3.1. Ping Request

A ping request is used to verify that the gatekeeper is configured properly to handle a named service. The ping request consists of the following:

```
POST ping/job-manager-name HTTP/1.1
Host: host-name
Content-Type: application/x-globus-gram
Content-Length: message-size

protocol-version: version
```

The values of the message-specific strings are

**job-manager-name**

The name of the service to have the gatekeeper check. The service name corresponds to one of the gatekeeper's configured grid-services, and is usually of the form "jobmanager-LRM".

**host-name**

The name of the host on which the gatekeeper is running. This exists only for compatibility with the HTTP/1.1 protocol.

**message-size**

The length of the content of the message, not including the HTTP/1.1 header.
**version**

The version of the GRAM protocol which is being used. For the protocol defined in this document, the value must be the string "2".

### 1.3.2. Job Request

A job request is used to scheduler a job remotely using GRAM. The ping request consists of the HTTP framing described above with the request-URI consisting of `job-manager-name`, where `job-manager name` is the name of the service to use to schedule the job. The format of a job request message consists of the following:

```
POST job-manager-name[@user-name] HTTP/1.1
Host: host-name
Content-Type: application/x-globus-gram
Content-Length: message-size

protocol-version: version
job-state-mask: mask
callback-url: callback-contact
rsl: rsl-description
```

The values of the emphasized text items are as below:

- **job-manager-name** The name of the service to submit the job request to. The service name corresponds to one of the gatekeeper's configured grid-services, and is usually of the form jobmanager-LRM.

- **user-name** Starting with GT4.0, a client may request that a certain account by used by the gatekeeper to start the job manager. This is done optionally by appending the @ symbol and the local user name that the job should be run as to the `job-manager-name`. If the @ and username are not present, then the first grid map entry will be used. If the client credential is not authorized in the grid map to use the specified account, an authorization error will occur in the gatekeeper.

- **host-name** The name of the host on which the gatekeeper is running. This exists only for compatibility with the HTTP/1.1 protocol.

- **message-size** The length of the content of the message, not including the HTTP/1.1 header.

- **version** The version of the GRAM protocol which is being used. For the protocol defined in this document, the value must be the string 2.

- **mask** An integer representation of the job state mask. This value is obtained from a bitwise-OR of the job state values which the client wishes to receive job status callbacks about. These meanings of the various job state values are defined in the GRAM Protocol API documentation.

- **callback-contact** A https URL which defines a GRAM protocol listener which will receive job state updates. The from a bitwise-OR of the job state values which the client wishes to receive job status callbacks about. The job status update messages are defined below.

- **rsl-description** A quoted string containing the RSL description of the job request.

### 1.3.3. Status Request

A status request is used by a GRAM client to get the current job state of a running job. This type of message can only be sent to a job manager's job-contact (as returned in the reply to a job request message). The format of a job request message consists of the following:
POST job-contact HTTP/1.1  
Host: host-name  
Content-Type: application/x-globus-gram  
Content-Length: message-size  
protocol-version: version

"status"

The values of the emphasized text items are as below:

job-contact The job contact string returned in a response to a job request message, or determined by querying the MDS system.

host-name The name of the host on which the job manager is running. This exists only for compatibility with the HTTP/1.1 protocol.

message-size The length of the content of the message, not including the HTTP/1.1 header.

version The version of the GRAM protocol which is being used. For the protocol defined in this document, the value must be the string 2.

1.3.4. Callback Register Request

A callback register request is used by a GRAM client to register a new callback contact to receive GRAM job state updates. This type of message can only be sent to a job manager’s job-contact (as returned in the reply to a job request message). The format of a job request message consists of the following:

POST job-contact HTTP/1.1  
Host: host-name  
Content-Type: application/x-globus-gram  
Content-Length: message-size  
protocol-version: version  
"register mask callback-contact"

The values of the emphasized text items are as below:

job-contact The job contact string returned in a response to a job request message, or determined by querying the MDS system.

host-name The name of the host on which the job manager is running. This exists only for compatibility with the HTTP/1.1 protocol.

message-size The length of the content of the message, not including the HTTP/1.1 header.

version The version of the GRAM protocol which is being used. For the protocol defined in this document, the value must be the string 2.

mask An integer representation of the job state mask. This value is obtained from a bitwise-OR of the job state values which the client wishes to receive job status callbacks about. These meanings of the various job state values are defined in the GRAM Protocol API documentation.

callback-contact A https URL which defines a GRAM protocol listener which will receive job state updates. The from a bitwise-OR of the job state values which the client wishes to receive job status callbacks about. The job status update messages are defined below.
1.3.5. Callback Unregister Request

A callback unregister request is used by a GRAM client to request that the job manager no longer send job state updates to the specified callback contact. This type of message can only be sent to a job manager's job-contact (as returned in the reply to a job request message). The format of a job request message consists of the following:

```
POST job-contact HTTP/1.1
Host: host-name
Content-Type: application/x-globus-gram
Content-Length: message-size

protocol-version: version
"unregister callback-contact"
```

The values of the emphasized text items are as below:

- **job-contact**: The job contact string returned in a response to a job request message, or determined by querying the MDS system.
- **host-name**: The name of the host on which the job manager is running. This exists only for compatibility with the HTTP/1.1 protocol.
- **message-size**: The length of the content of the message, not including the HTTP/1.1 header.
- **version**: The version of the GRAM protocol which is being used. For the protocol defined in this document, the value must be the string "2".
- **callback-contact**: A https URL which defines a GRAM protocol listener which should no longer receive job state updates. The from a bitwise-OR of the job state values which the client wishes to receive job status callbacks about. The job status update messages are defined @ref globus_gram_protocol_job_state_updates "below".

1.3.6. Job Cancel Request

A job cancel request is used by a GRAM client to request that the job manager terminate a job. This type of message can only be sent to a job manager's job-contact (as returned in the reply to a job request message). The format of a job request message consists of the following:

```
POST job-contact HTTP/1.1
Host: host-name
Content-Type: application/x-globus-gram
Content-Length: message-size

protocol-version: version
"cancel"
```

The values of the emphasized text items are as below:

- **job-contact**: The job contact string returned in a response to a job request message, or determined by querying the MDS system.
- **host-name**: The name of the host on which the job manager is running. This exists only for compatibility with the HTTP/1.1 protocol.
The length of the content of the message, not including the HTTP/1.1 header.

The version of the GRAM protocol which is being used. For the protocol defined in this document, the value must be the string 2.

1.3.7. Job Signal Request

A job signal request is used by a GRAM client to request that the job manager process a signal for a job. The arguments to the various signals are discussed in the protocol library documentation. The format of a job request message consists of the following:

POST job-contact HTTP/1.1
Host: host-name
Content-Type: application/x-globus-gram
Content-Length: message-size

protocol-version: version
"signal"

The values of the emphasized text items are as below:

job-contact The job contact string returned in a response to a job request message, or determined by querying the MDS system.

host-name The name of the host on which the job manager is running. This exists only for compatibility with the HTTP/1.1 protocol.

message-size The length of the content of the message, not including the HTTP/1.1 header.

version The version of the GRAM protocol which is being used. For the protocol defined in this document, the value must be the string 2.

signal A quoted string containing the signal number and its parameters.

1.3.8. Job State Updates

A job status update message is sent by the job manager to all registered callback contacts when the job's status changes. The format of the job status update messages is as follows:

POST callback-contact HTTP/1.1
Host: host-name
Content-Type: application/x-globus-gram
Content-Length: message-size

protocol-version: version
job-manager-url: job-contact
status: status-code
failure-code: failure-code

The values of the emphasized text items are as below:

callback-contact The callback contact string registered with the job manager either by being passed as the callback-contact in a job request message or in a callback register message.
host-name

The host part of the callback-contact URL. This exists only for compatibility with the HTTP/1.1 protocol.

message-size

The length of the content of the message, not including the HTTP/1.1 header.

version

The version of the GRAM protocol which is being used. For the protocol defined in this document, the value must be the string 2.

job-contact

The job contact of the job which has changed states.

1.3.9. Proxy Delegation

A proxy delegation message is sent by the client to the job manager to initiate a delegation handshake to generate a new proxy credential for the job manager. This credential is used by the job manager or the job when making further secured connections. The format of the delegation message is as follows:

```
POST callback-contact HTTP/1.1
Host: host-name
Content-Type: application/x-globus-gram
Content-Length: message-size

protocol-version: version
"renew"
```

If a successful (200) reply is sent in response to this message, then the client will proceed with a GSI delegation handshake. The tokens in this handshake will be framed with a 4 byte big-endian token length header. The framed tokens will then be wrapped using the GLOBUS_IO_SECURE_CHANNEL_MODE_SSL_WRAP wrapping mode. The job manager will frame response tokens in the same manner. After the job manager receives its final delegation token, it will respond with another response message that indicates whether the delegation was processed or not. This response message is a standard GRAM response message.

1.3.10. Security Attributes

The following security attributes are needed to communicate with the Gatekeeper:

- Authentication must be done using GSSAPI mutual authentication
- Messages must be wrapped with support for the delegation message. When using Globus I/O, this is accomplished by using the the GLOBUS_IO_SECURE_CHANNEL_MODE_GSI_WRAP wrapping mode.

1.4. Job State Model

As the GRAM service processes a job, the job undergoes a series of state transitions. These states and their meanings follow:
Table 4.1. GRAM Job States

<table>
<thead>
<tr>
<th>State</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>GLOBUS_GRAM_PROTOCOL_JOB_STATE_UNSUBMITTED</td>
<td>Initial job state</td>
